

# ENERGY STAR<sup>®</sup> Program Requirements Product Specification for Large Network Equipment

## Preliminary Approach For Determining Energy Efficiency Rev. Oct-2012

### 1 OVERVIEW

The following test method shall be used for determining product compliance with requirements in the ENERGY STAR Eligibility Criteria for Large Network Equipment (LNE).

**Note:** This document outlines a proposed approach that is consistent with relevant industry test procedures. It contains several noteboxes which identify specific issues that DOE is seeking comment on. Additionally, DOE welcomes comments from stakeholders on any ambiguities, suggested revisions, or concerns with the proposed test method. As the process moves forward, DOE will be working with manufacturers to view how they perform LNE testing, and will be reaching out to all stakeholders to have more in-depth conversations about the test method.

### 2 APPLICABILITY

The proposed test method shall be used to determine the energy efficiency of all products under the ENERGY STAR Product Specification for Large Network Equipment. Large Network Equipment is defined in this test method in section 3.B)4).

**Note:** EPA and DOE have determined that the specification for LNE will be drafted when the LNE Test Method is nearly final. Therefore, the Applicability (Scope) of both the test method and the specification will be discussed during development of the test method.

DOE has developed a preliminary LNE definition for discussion, proposed in section 3.B) 4). DOE is seeking feedback on ways to appropriately identify certain classes of network equipment as Large Network Equipment, i.e., as opposed to Small Network Equipment.

### 3 DEFINITIONS

Unless otherwise specified, all terms used in this document are consistent with the definitions in the ENERGY STAR Eligibility Criteria for Large Network Equipment Version 1.0 Draft 1.

**Note:** For initial discussion, the acronyms and definitions below have been included in the test method. The entire definitions section will be moved to the eligibility criteria upon development of the Version 1.0 Draft 1 specification.

DOE has reviewed the ATIS and ECR Initiative test procedures for LNE and has tentatively decided to utilize applicable sections of these documents in this Preliminary Approach. DOE has determined that the definitions contained within the referenced publications are consistent and has therefore incorporated definitions from ATIS and the ECR Initiative into this section.

DOE requests comment on the applicability, consistency and clarity of the proposed definitions.

#### A) Acronyms and Units:

- 1) ac: Alternating Current

- 33 2) ATIS: Alliance for Telecommunications Industry Solutions
- 34 3) bps: Bits per second
- 35 4) C: Celsius
- 36 5) dc: Direct Current
- 37 6) DOE: U.S. Department of Energy
- 38 7) ECR: Energy Consumption Rating
- 39 8) EPA: U.S. Environmental Protection Agency
- 40 9) Gbps: Gigabits per second
- 41 10) Hz: Hertz
- 42 11) IMIX: Internet Mix
- 43 12) NDR: Non-Drop Rate
- 44 13) OSI: Open Systems Interconnection
- 45 14) PDU: Power Distribution Unit
- 46 15) PSU: Power Supply Unit
- 47 16) RMS: Root Mean Square
- 48 17) TEER: Telecommunications Energy Efficiency Ratio
- 49 18) UPS: Uninterruptible Power Supply
- 50 19) UUT: Unit Under Test
- 51 20) V: Volts
- 52 21) W: Watt

53 B) Definitions:

- 54 1) Computer Network: A network of data processing nodes that are interconnected for the purpose  
55 of data communication.
- 56 2) Idle State: A state of operation in which the product is powered on, ready to pass traffic, but is not  
57 currently passing traffic.
- 58 3) Internet Mix (IMIX) Traffic: A stateless traffic profile that contains a mixture of frame sizes  
59 statistically similar to a composition observed in the Internet<sup>1</sup>.
- 60 4) Large Network Equipment: Network Equipment that is rack-mounted, intended for use in standard  
61 equipment racks, or contains more than eleven (11) ports for wired network.
- 62 5) Maximum Demonstrated Throughput: The highest achievable system throughput at Non-Drop  
63 Rate, measured in bits per second (bps).
- 64 6) Network Device: A single functional unit of network equipment.
- 65 7) Network Equipment: A category of electronically powered devices which organize and schedule  
66 the coherent transmission of data within a single, or between at least two, computer networks.
- 67 8) Non-Drop Rate (NDR): The observed system throughput at which no packet drops are recorded.
- 68 9) Port Throughput: The sustained rate of traffic (in bps) passing through a port in either direction,  
69 including the minimally needed line overhead.
- 70 10) Port Utilization: The port throughput expressed as a percentage of its theoretical maximum.

---

<sup>1</sup> For further information regarding IMIX, refer to Spirent Communications – Test Methodology Journal: IMIX (Internet Mix) Journal, March 2006.

- 71 11) Router: A network device that determines the optimal path along which network traffic should be  
72 forwarded as its primary function. Routers forward packets from one network to another based on  
73 network layer information.
- 74 12) Switch: A network device that filters, forwards, and floods frames based on the destination  
75 address of each frame as its primary function. The switch operates at the data link layer of the  
76 Open Systems Interconnection (OSI) model.
- 77 13) System Throughput: Sum of link-rate throughput on all system ports in the egress direction (bps),  
78 including all protocol overhead.
- 79 14) System Utilization: The system throughput expressed as a percentage of the system's theoretical  
80 maximum.
- 81 15) Traffic Profile: The statistical distribution of the size/type of the data packet load sent through  
82 equipment under test.
- 83 16) Unit Under Test (UUT): The network equipment device being tested.

#### 84 4 TEST SETUP

- 85 A) Input Power: Input power shall be as specified in Table 1 and Table 2. The frequency for input power  
86 shall be as specified in Table 3.

87 **Table 1: Input Power Requirements for Products with Nameplate Rated Power Less Than**  
88 **or Equal to 1500 W**

Product Type/Market	Supply Voltage	Voltage Tolerance	Maximum Total Harmonic Distortion
North America, Taiwan, Europe, Australia, New Zealand	230 V ac and/or 115 V ac	+/- 1.0 %	2.0 %
Optional Testing Conditions For Ac-Dc Japanese Market	100 V ac		
Dc systems*	48 V dc	+/- 1.0 V	
	380 V dc	+/- 4.0 V

111

- B) Ambient Temperature: Ambient temperature shall be within 23 °C ± 5 °C over the duration of the test.
- C) Relative Humidity: Relative humidity shall be within 15% and 80%.
- D) Power Meter: The power meter shall report true Root Mean Square (RMS) power and at least two of the following measurement units: voltage, current, and power factor. Power meters shall possess the following attributes:
  - 1) Calibration: The meter shall have been calibrated within a year of the test date, by a standard traceable to National Institute of Standards and Technology (USA) or a counterpart national metrology institute in other countries.
  - 2) Crest Factor: An available current crest factor of 3 or more at its rated range value. For analyzers that do not specify the current crest factor, the analyzer must be capable of measuring an amperage spike of at least 3 times the maximum amperage measured during any 1 second sample.
  - 3) Minimum Frequency Response: 3.0 kHz.
  - 4) Minimum Resolution:
    - a) 0.01 W for measurement values less than 10 W;

- 112 b) 0.1 W for measurement values from 10 W to 100 W; and  
113 c) 1.0 W for measurement values greater than 100 W.
- 114 5) Logging: The meter must be capable of reading and logging at least 1 set of power  
115 measurements per second, and each measurement shall be recorded in watts. Each recorded  
116 data point shall be an average of the measured power, using a data averaging interval that is  
117 equal to the time period between each subsequent power measurement.
- 118 6) Measurement Accuracy: The measurement uncertainty introduced by the instrument that  
119 measures the input power supplied to the product under test, including any external shunts, must  
120 adhere to the following standards:
- 121 a) Power measurements with a value greater than or equal to 0.5 W shall be made with an  
122 uncertainty of less than or equal to 2% at the 95% confidence level.
- 123 b) Power measurements with a value less than 0.5 W shall be made with an uncertainty of less  
124 than or equal to 0.01 W at the 95% confidence level
- 125 E) Traffic Generator/Analyzer: All data ports on the UUT shall be connected to a traffic  
126 generator/analyzer for the full test duration.

127 **Note:** Sections 4.E), 5.1.F), and 5.2.D) of this test method state that all data ports on the UUT must be  
128 connected to the traffic generator/analyzer during testing. DOE recognizes that this configuration may not  
129 be representative of how LNE is connected during normal operation, and is requesting stakeholder  
130 feedback regarding the number of UUT data ports used during testing. Specifically, how many ports  
131 should be connected during testing? How does the number of connected ports affect LNE performance  
132 and power consumption?

- 133 1) Number of Ports: The traffic generator/analyzer shall have a total number of properly functioning  
134 ports which is equal to or greater than the total number of data ports on the UUT.
- 135 2) Data Format: The traffic generator/analyzer shall be capable of generating test data which are  
136 correctly formatted for processing by the UUT.
- 137 a) Available Packet Sizes: The traffic generator/analyzer shall be capable of generating test  
138 data with packet sizes in the range of 28 Bytes to 1500 Bytes.
- 139 b) Generated Packet Size Statistical Distribution: The traffic generator/analyzer shall be capable  
140 of generating test data consisting of packet sizes whose generation frequency is statistically  
141 described by the Accurate IMIX distribution, defined in Table 4.
- 142 i. Ranged Packet Sizes: The last three rows of this table represent a range of packet sizes.  
143 Any size within the indicated range shall be generated with equal (uniform) probability if a  
144 packet is to be generated from one of these rows.
- 145 *Example: There is a 10.8% chance that a packet will be generated with a size within the*  
146 *range of 40 and 80 Bytes. If a packet with a size in this range is to be generated, all sizes*  
147 *from 40 to 80 will have an equal chance of being generated. Therefore, the overall*  
148 *probability that a packet will be generated that is 55 Bytes long is:  $(10.8\% / 41) \approx 0.26\%$ .*

149 **Note:** DOE understands that the costs to acquire a traffic generator/analyzer capable of generating  
150 Accurate IMIX traffic with enough ports to support full capacity testing can be high. DOE is interested in  
151 stakeholder feedback on other possible methods for generating network traffic that are representative of  
152 normal operation. DOE is also interested in feedback on test setups other than a single traffic  
153 generator/analyzer that can support full capacity testing.

154  
155

Table 4: Accurate IMIX Packet Distribution<sup>2</sup>

Packet Size (Bytes)	Proportion of Total Generated Packets	Proportion of Total Generated Bandwidth
28	1.20%	0.08%
40	35.50%	3.51%
44	2.00%	0.22%
48	2.00%	0.24%
52	3.50%	0.45%
552	0.80%	1.10%
576	11.50%	16.40%
628	1.00%	1.50%
1420	3.00%	10.50%
1500	10.00%	37.10%
40 – 80 (range)	10.80%	1.60%
80 – 576 (range)	11.80%	9.60%
576 – 1500 (range)	6.90%	17.70%

157 **Note:** DOE is proposing the use of an IMIX traffic model for testing Large Network Equipment. An IMIX  
 158 traffic model is a statistical cross-section of the packet sizes, in bytes, which are generated during testing.  
 159 Each IMIX traffic model will dictate the probability that a packet of a certain byte length will be generated  
 160 at a port at any given point in time.

161 DOE is presently considering the use of IMIX traffic models listed in Annex C IMIX Traffic of ATIS –  
 162 0600015.03.200. This document contains three tables, each of which describes the statistical cross  
 163 section of measured internet packet sizes at a different level of granularity. The three tables represent  
 164 “Simple IMIX”, “Complete IMIX (informative)”, and “Accurate IMIX (informative)”, which when compared to  
 165 realistic Internet traffic have correlation values of 0.892, 0.985, and 0.999 respectively. DOE is presently  
 166 considering the use of the Accurate IMIX due to its high correlation with realistic internet traffic, but is  
 167 seeking feedback from stakeholders as to whether this would constitute “normal use” for Large Network  
 168 Equipment.

169 The last three rows of Table 4 specify a range of possible packet size values that can be generated. As it  
 170 is currently written in ATIS, the ranges are 40-80, 80 to 576, and 576 to 1500. This indicates that the  
 171 packet sizes of 80 and 576 are counted twice. If the Accurate IMIX traffic model is used, DOE proposes  
 172 that ranges be rewritten as: 40 to 79, 80 to 575, and 576 to 1500. This minor modification would divide  
 173 the packet sizes into three non-overlapping ranges. DOE requests comment on this proposal.

174 3) Throughput: The traffic generator/analyzer shall be capable of generating, transmitting to,  
 175 receiving from, and analyzing test data on all connected ports at a rate exceeding the UUT’s  
 176 maximum rated throughput.

177 a) Throughput Incremental Granularity: The traffic generator/analyzer shall be capable of  
 178 increasing and decreasing the data throughput transmitted to all the UUT’s connected ports

<sup>2</sup> “Table C.3: Accurate IMIX (Informative)”, Annex C: IMIX Traffic, ATIS – 0600015.03.2009

179 by an incremental amount that is equal to or less than 1% of the UUT's maximum rated  
180 throughput.

181 **Note:** DOE is requesting stakeholder feedback on whether 1% of maximum rated throughput is an  
182 appropriate load increment requirement for testing.

183 4) Data Recording: The traffic generator/analyzer shall be capable of accurately measuring and  
184 recording the test data throughput at each UUT port to verify that the correctly specified test data  
185 throughput is consistently applied to each port during testing.

## 186 5 TEST CONDUCT

### 187 5.1 Active Mode Efficiency Test Configuration

188 Power and efficiency shall be tested and reported for the Large Network Equipment being tested. Testing  
189 shall be conducted as follows:

190 A) As-shipped Condition: Products shall be tested in their "as-shipped" configuration, which includes  
191 both hardware configuration and system settings, unless otherwise specified in this test method.

192 **Note:** DOE recognizes that many LNE may require configuration prior to first use. Therefore, DOE  
193 requests stakeholder feedback on whether it is reasonable to expect manufacturers to ship devices in a  
194 "ready-to-function" state. Specifically, DOE is requesting information on initial configuration setup for  
195 different types of LNE products.

196 B) Measurement Location: All power measurements shall be taken at a point between the ac or dc  
197 power source and the UUT.

198 C) Air Flow Management: Any air flow directly surrounding the UUT during testing shall only be  
199 generated by fans or cooling devices that are standard components of the UUT. The use of external  
200 fans or cooling devices to purposefully direct air at, or away from, the UUT during testing is  
201 prohibited.

202 **Note:** The Air Flow Management requirement is included to clarify that external cooling equipment, such  
203 as localized air fans directed at the UUT, are not permitted. However, DOE recognizes that large data  
204 center equipment is generally cooled to avoid overheating the components and data center space.

205 DOE has specified an ambient temperature requirement during testing (Section 4.B)). DOE is requesting  
206 feedback on if the specification in Section 4.B) is sufficient, or if additional air flow specification(s) is(are)  
207 necessary. If additional specifications are necessary, DOE requests specifics, supported by literature  
208 references.

209 D) Power Supplies: All power supply units (PSUs) must be connected and operational.

210 1) UUTs with Multiple PSUs: All power supplies must be connected to the ac or dc power source  
211 and operational during the test. If necessary, a Power Distribution Unit (PDU) may be used to  
212 connect multiple power supplies to a single source. If a PDU is used, any overhead electrical use  
213 from the PDU shall be included in the power measurement of the UUT. When the UUT is a  
214 specific module in a modular (or racked) system, any unused power supplies shall be  
215 disconnected.

216 E) Power Management: All power management and/or power-saving features available on the UUT shall  
217 be disabled during testing.

218 1) The entire Large Network Equipment Test Method may be voluntarily repeated with power  
219 management and/or power-saving features enabled.

220 **Note:** DOE recognizes that LNE may be commonly designed with optional power management and/or  
221 power-saving features. When enabled, these features may configure the system to operate in a mode  
222 which consumes less energy. LNE designed with power-saving features may require advanced  
223 configuration before it can be used. There may also be many available combinations of power-saving  
224 modes available on each LNE. In order to provide a more consistent test method, DOE is proposing that  
225 power-saving options be disabled during testing. This ensures that all LNE are compared at the same  
226 base-line operating mode. DOE requests stakeholder feedback on whether power management and/or  
227 power-saving features are commonly available in LNE, what functions these features perform, and if  
228 these features are enabled by default when shipped.

229 DOE proposes that the test method can be voluntarily repeated with power management and/or power-  
230 saving features enabled if such features are available.

231 F) I/O and Network Connection: All UUT ports shall be in an active state and passing or ready to pass  
232 traffic. All ports shall be connected to the traffic generator/analyzer for the entirety of the test.

233 1) System Configuration Ports: Any port on the UUT which is solely intended for infrequent device  
234 configuration may be left disconnected during testing.

235 G) Workload Generation: A traffic generator/analyzer conforming to the requirements listed in section  
236 4.E) shall be used to simulate traffic and collect the performance-related results according to the test  
237 conditions. Configure the traffic generator/analyzer for the correct traffic workload and traffic profile  
238 based on the data in Table 4.

## 239 5.2 UUT Preparation

240 A) Record the UUT manufacturer, model name, and configuration details including, but not limited to,  
241 number of ports, port throughput, additional built in interface ports, and number of fans.

242 B) If the UUT is a rack device, install it in a test rack. If the UUT is not a rack device, place it in a stable  
243 location where it will not be disturbed. Once set up, the UUT shall not be physically moved until  
244 testing is complete.

245 1) If the UUT is a blade switch, then the UUT shall be populated in the first slot (i.e. slot #1) of the  
246 blade chassis and shall not be physically moved until testing is complete.

247 **Note:** DOE is interested in feedback from stakeholders on the proposed test configuration of blade  
248 switches. DOE is also interested in information regarding other possible types of Large Network  
249 Equipment in the market which use the blade form factor. What other factors need to be taken into  
250 consideration when testing blade-based equipment as opposed to standard rack-mount equipment?

251 C) Configure the traffic generator/analyzer for the correct traffic workload and profile as described in  
252 section 4.E).

253 D) Connect all UUT ports to the traffic generator/analyzer in either the full mesh topology or the dual-  
254 group partial mesh topology based on its product class using Table 5 or Table 6.

255 1) Full mesh topology shall be used when each of the UUT's ports are designed to perform equal  
256 roles and are capable of handling the same traffic bandwidth. During testing, traffic is permitted  
257 between all ports on the UUT. Example equipment that may be tested using this topology include  
258 core routers and carrier Ethernet switches.

259 Note: Full mesh topology is defined as "T1 (full mesh)" in Appendix C of ECR Initiative – Network  
260 and Telecom Equipment – Energy and Performance Assessment Draft 3.0.1, December 14, 2010

261 2) Dual-group partial mesh topology shall be used when the UUT's ports can be functionally  
262 partitioned into two groups, with all ports in either group capable of performing equal roles and  
263 handling the same traffic bandwidth. During testing, traffic is not permitted between any ports on  
264 the UUT which are in the same functionally partitioned group. Example equipment that may be  
265 tested using this topology includes edge routers and access routers.

266 Note: Dual-group partial mesh topology is defined as “T2 (dual-group partial mesh)” in Appendix  
 267 C of ECR Initiative – Network and Telecom Equipment – Energy and Performance Assessment  
 268 Draft 3.0.1, December 14, 2010.  
 269

270 **Table 5: Class Definitions and Connection Topologies for Routers<sup>3</sup>**

Class	Topology
Access Router	<i>TBD</i>
Edge Router	Dual-Group Partial Mesh
Core Router	Full Mesh

271  
 272 **Table 6: Class Definitions and Connection Topologies for Ethernet Switches<sup>3</sup>**

Class	Topology
Access or High Speed Access Switch	<i>TBD</i>
Distribution/ Aggregation Switch	Dual-Group Partial Mesh
Core Switch	Full Mesh
Data Center Switch	Full Mesh

273 **Note:** DOE is interested in receiving feedback on whether the proposed topologies are representative of  
 274 LNE connections in normal operation. Stakeholders are also encouraged to comment on other topologies  
 275 that could be used to connect the UUT to the traffic generator/analyzer. Furthermore, are the  
 276 qualifications outlined in the ECR Initiative document clear enough to determine which topology to use  
 277 when testing a given UUT?

278 DOE would like to point out that the term *TBD* in Table 5 and Table 6 indicate that there presently no  
 279 designated topology for the Access router/switch class. DOE is interested in receiving feedback on what  
 280 sort of topology would be appropriate for testing an Access router and an Access switch.

- 281 E) Connect the UUT to an appropriate ac or dc voltage source using the following guidelines:
  - 282 1) No uninterruptible power supply (UPS) units shall be connected between the power meter and
  - 283 the UUT;
  - 284 2) The power meter shall remain connected until all testing is complete;
  - 285 3) Power values shall be recorded from the power meter in a way that is consistent with the
  - 286 requirements in section 4.D)5) of this document.
- 287 F) Verify that the UUT is configured in its as-shipped configuration.
- 288 G) Record the input root mean square (rms) voltage and input frequency.

<sup>3</sup> Appendix C of ECR Initiative – Network and Telecom Equipment – Energy and Performance Assessment Draft 3.0.1, December 14, 2010

289 **6 TEST PROCEDURES FOR ALL PRODUCTS**

290 **6.1 Power and Efficiency Testing**

- 291 A) Power on the UUT, either by switching it on or connecting it to mains power.  
292 B) Let the UUT stabilize for 15 minutes.

293 **Note:** ATIS requires a minimum UUT warm-up/stabilization time of 15 minutes, while the ECR Initiative  
294 requires at least 4 hours to settle potential temperature and humidity differences, before testing. DOE is  
295 interested in receiving stakeholder feedback on the benefits provided by a four hour stabilization  
296 requirement, compared to a 15 minute stabilization requirement.

297 In order to minimize the total testing time, DOE is proposing a stabilization time of 15 minutes, based on  
298 the ATIS test procedure. DOE is interested in receiving feedback as to whether this is an appropriate  
299 amount of time required for most LNE to power on, complete any boot/test sequences, and reach  
300 temperature equilibrium.

301 C) Qualification: Determine the maximum load ( $L_{max}$ ) that can be sustained at Non-Drop Rate (NDR).  
302 Any method may be used to obtain this value, but the method used shall be reported. There is no  
303 time limit for this run. The run is complete after  $L_{max}$  is determined. Record  $L_{max}$ .

304 D) The following tests shall be completed in the order specified and shall have no greater than 300  
305 seconds idle time between them.

306 1) Full Load:

- 307 a) Apply  $L_{max}$ , obtained in section 6.1C) to the UUT for 15 minutes.  
308 b) Record power values over the entire 15 minute test period.  
309 c) Calculate and report the average power value ( $P_{100}$ ).

310 2) Low Utilization:

- 311 a) Determine the low utilization percentage (U%) for the UUT, as defined in Table 5 for Routers  
312 and in Table 6 for Switches. Determination of U% is dependent upon the UUT product type  
313 and class.

314 **Note:** The ATIS test procedure currently defines qualitative product classes for LNE, based largely on the  
315 product's application/end-use.

316 For testing, DOE is interested in classifying LNE using more consistent and quantitative methods. DOE  
317 requests stakeholder feedback on alternate, quantitative methods by which to classify different types of  
318 LNE for testing..

- 319 b) Calculate and report the low utilization throughput ( $L_u$ ), by multiplying  $L_{max}$  and U% ( $L_u =$   
320  $U\% * L_{max}$ )  
321 c) Run the test for 15 minutes.  
322 d) Record power values for the entire 15 minute period.  
323 e) Calculate and report the average value ( $P_u$ ).

324

325 **Table 7: Class Definitions, TEER calculation parameters, and load parameters for Routers<sup>4</sup>**

Class	Partial-Utilization (U%)	Weight Multipliers <sup>5</sup> a, b, c
Access Router	10	a=0.10; b=0.80; c=0.10
Edge Router	10	a=0.15; b=0.75; c=0.10
Core Router	30	a=0.10; b=0.80; c=0.10

326  
327 **Table 8: Class Definitions, TEER calculation parameters, and load parameters for Ethernet<sup>6</sup>**  
328 **Switches**

Class	Partial-Utilization (U%)	Weight Multipliers <sup>5</sup> a, b, c
Access or High Speed Access Switch	10	a=0.10; b=0.80; c=0.10
Distribution/ Aggregation Switch	10	a=0.15; b=0.75; c=0.10
Core Switch	30	a=0.15; b=0.75; c=0.10
Data Center Switch	30	a=0.10; b=0.80; c=0.10

329 **Note:** DOE is interested in stakeholder feedback regarding whether the utilization levels provided in in  
330 Tables 7 and 8 are representative of normal operation. DOE is also interested in feedback on any  
331 additional utilization levels that should be tested.

332 3) Idle:

333 a) Remove the load by idling the packet rate on all configured ports record power values for 15  
334 minutes. Load reduction shall not be achieved by disconnecting or shutting down ports.

335 b) Calculate and report the average value ( $P_{idle}$ ).

336 E) If packet loss occurs during any of the tests specified in section 6.1 E), F), and G), the UUT must be  
337 retested beginning with section 6.1C).

338

<sup>5</sup> Weight multipliers used in 7.A) Equation 1

<sup>6</sup> Table 2, Section 5.2 of the ATIS-0600015.03.2009 standard

339 **7 METRIC**

340 **A)** The Telecommunications Energy Efficiency Ratio shall be calculated and reported as follows:

341 **Equation 1: TEER Metric Calculation**

342

$$TEER = \frac{L_{max}}{a * P_{idle} + b * P_u + c * P_{100}}$$

343 *Where:*

344 *Where:*

- 345 • *a, b, and c are weight coefficients selected such that  $a + b + c = 1$*
- 346     o *Appropriate values are specified in Tables 5 and 6*
- 347 •  *$L_{max}$  is the maximum throughput of the UUT (Gbps)*
- 348     o *Defined in section 6.1.C)*
- 349 •  *$P_{100}$  is the power consumption during the Full Load Test (W)*
- 350     o *Defined in section 6.1.D)1)*
- 351 •  *$P_u$  is the power consumption during the Low Utilization Test (W)*
- 352     o *Defined in section 6.1.D)2)*
- 353 •  *$P_{idle}$  is the power consumption during the Idle Test (W)*
- 354     o *Defined in section 6.1.D)3)*

355

356  
357

**Note:** Additional information about the TEER calculation and a, b, c can be found in section 5.2 “TEER Metric Definition” of the ATIS-0600015.03.2009 standard.

358  
359  
360  
361

The ECR Initiative proposes a similar metric, called the Energy Consumption Rating (ECR), as well as two variations on this metric: ECR-Variable Load (ECR-VL) and ECR-Extended Idle (ECR-EX). The ECR variation, shown in Equation 2, is most similar to TEER. A comparison of the TEER and ECR-VL metrics is shown in Table 9.

362  
363

**Equation 2: ECR-VL Metric Calculation**

$$ECR-VL = \frac{a * P_{100} + b * P_{50} + c * P_{30} + d * P_{10} + e * P_{idle}}{a * L_{max} + b * L_{50} + c * L_{30} + d * L_{10}}$$

364  
365

**Table 9: Comparison of TEER and ECR-VL Metrics**

Metric	TEER	ECR-VL
<b>Unit used for metric</b>	Gigabits-per-second per watt (Gbps/W)	Watts per gigabit-per-second (W/Gbps)
<b>Utilization levels corresponding to the power consumption measurements included in the metric</b>	100%, [10% or 30%], 0%	100%, 50%, 30%, 10%, 0%
<b>Weighting applied to power consumption measurements used to calculate metric</b>	All power measurements are weighted based on product class  (a, b, c)	All power measurements are weighted based on product class  (a, b, c, d, e)
<b>Utilization levels corresponding to the throughputs included in the metric</b>	100%	100%, 50%, 30%, 10%
<b>Weighting applied to utilization levels measurements used to calculate metric</b>	No weighting applied to throughput	All throughputs are weighted based on product class  (a, b, c, d)

DOE is proposing the use of TEER in the Preliminary Approach since it requires fewer weight-constants and focuses more specifically on a utilization level for each product class. This will simplify determination of the required weight-constants, create greater test consistency within each product class, and reduce overall testing time. DOE requests feedback from stakeholders on the proposed TEER metric. Specifically, does TEER provide a more representative efficiency metric than ECR-VL?
